

Decisions inside decisions

Nested logic

```
if num % 2 == 0:
    if salary > 5:
        print("Great")
```

Use it when one decision depends on another.

The inner condition runs only after the outer one is true.

What is nested if?

Indentation shows which block owns which code.

Outer false? Inner skipped.

Odd number

```
num = 7
if num % 2 == 0:
    if salary > 5:
        print("Great Job")
```

Control flow

```
7 % 2 == 0
False
skip inner block
no salary check
```

Python never enters the nested block.

Even first. Salary next.

Path A

```
num = 8
salary = 6
if num % 2 == 0:
    if salary > 5:
        print("Great Job")
```

Path B

```
num = 8
salary = 5
if num % 2 == 0:
    if salary > 5:
    else:
        print("Better luck")
```

The inner salary test exists only inside the even branch.

Cheat Sheet

Python nested if

Basic syntax

```
if outer_condition:
    if inner_condition:
        code_block
```

Outer condition

False means inner code is skipped.

Indentation

Each indent level changes the hierarchy.

Use case

Check a second rule only after the first passes.

Example output

Great Job / Better luck next time

Save this for your Python journey.
