

Cleaner value matching

```
Python 3.10+

match command:
    case "start":
        run()
    case "stop":
        pause()
    case _:
        show_help()
```

match-case is Python's readable value matcher.

It keeps long if-elif chains easier to scan.

Before match there was switch

C / Java style

```
switch(day) {  
  case 1:  
    print("Mon");  
    break;  
  case 2:  
    print("Tue");  
    break;  
}
```

The idea

choose by value
one matching branch
avoid messy chains
break prevents
fall-through

Python match gives this idea a clean Python syntax.

if-elif VS match

Old way

```
day = 2
if day == 1:
    print("Mon")
elif day == 2:
    print("Tue")
else:
    print("Invalid")
```

New way

```
day = 2
match day:
    case 1:
        print("Mon")
    case 2:
        print("Tue")
    case _:
        print("Invalid")
```

match groups the value and its cases in one place.

Default uses case _

match_demo.py

```
command = "save"
match command:
    case "open":
        print("Opening")
    case "save":
        print("Saving")
    case _:
        print("Incorrect option")
```

case value

Runs when the subject equals that value.

case _

Catches anything not matched above.

No else

The underscore is the fallback branch.

When should you use it?

Great for match

```
match role:
    case "admin":
        dashboard()
    case "editor":
        workspace()
    case _:
        guest_view()
```

Keep if for logic

```
if age >= 18
and salary > 5:
    approve()
else:
    review()
```

Use match for value choices; use if for complex conditions.

Cheat Sheet

Python match-case

Basic syntax

```
match value:
    case option_1:
        block_1
    case option_2:
        block_2
    case _:
        default_block
```

Version

Introduced in Python 3.10.

Default

Use case _ instead of else.

Readable

Cleaner for many fixed values.

Still use if

Better for ranges and boolean logic.

Save this for your Python journey.
